Abstract

The MIGSA package allows to perform a massive and integrative gene set analysis over several experiments and gene sets simultaneously. It provides a common gene expression analytic framework that grants a comprehensive and coherent analysis. Only a minimal user parameter setting is required to perform both singular and gene set enrichment analyses in an integrative manner by means of enhanced versions of the best available methods, i.e. dEnricher and mGSZ respectively.

One of the greatest strengths of this big omics data tool is the availability of several functions to explore, analyze and visualize its results in order to facilitate the data mining task over huge information sources.

The MIGSA package also allows to easily load the most updated gene sets collections from several repositories.

Keywords: singular enrichment analysis, over representation analysis, gene set enrichment analysis, functional class scoring, big omics data, r package, bioconductor.

1. Introduction

The functional analysis methodology allows researchers to gain biological insight from a list of deregulated gene sets between experimental conditions of interest. As suggested by (Rodriguez et al. 2016) both singular enrichment analysis (SEA) and gene set enrichment analysis (GSEA) must be performed over the same dataset in order to gain as much biological insight as possible. This strategy is known as Integrative Functional Analysis (IFA) and integrates into the same analysis with enhanced versions of the dEnricher (Fang and Gough 2014) and mGSZ (Mishra et al. 2014) methods.

At present, there are several freely available datasets which provide data over the same disease, characteristic of interest (e.g. survival), or subjects studied over several different platforms. The Cancer Genome Atlas (TCGA) among other projects makes possible the study and comparison in a massive way of these datasets, not only among them but, also against our own population of interest. This unprecedented opportunity allows researchers to search for
common functional patterns between these studies, or, more interestingly, particular patterns of our experiment in question. However, this type of approach has not been implemented in any existing tool yet, leaving aside valuable biological information that might assist research hypotheses.

Here, we present a Massive and Integrative Gene Set Analysis tool called MIGSA. It allows to evaluate and compare, massively and transparently, a large collection of datasets coming from diverse sources, maintaining the gene set enrichment ideas of IFA and minimizing parameter settings. In addition, it includes a gene ranking score alternative for RNAseq data by integrating the Voom+Limma methodological approach. It provides an enhanced version of mGSZ (MIGSAmGSZ) faster than the default implementation, in order to speed up even more its execution, MIGSA can be run using multicore architectures. In this sense it can be applied over a large collection of datasets on many gene sets in a fast way. Finally, MIGSA provides several user-friendly methods to easily explore and visualize results at gene set, dataset and individual gene level to aid researchers in their biological hypothesis understanding.

2. Preliminaries

2.1. Citing MIGSA

MIGSA implements a body of methodological research by the authors and co-workers. Citations are the main means by which the authors receive professional credit for their work. The MIGSA package can be cited as:

2.2. Installation

MIGSA is a package for the R computing environment and it is assumed that you have already installed R. See the R project at http://www.r-project.org. To install the latest version of MIGSA, you will need to be using the latest version of R.

MIGSA is part of the Bioconductor project at http://www.bioconductor.org. (Prior to R 3.4).

To get MIGSA package you can type in an R session:

```r
> ## try http:// if https:// URLs are not supported
> if (!requireNamespace("BiocManager", quietly=TRUE))
+   install.packages("BiocManager");
> BiocManager::install("MIGSA");
```

2.3. Class definitions

MIGSA basically consists of six classes and various functions that interact with them. The following is a simplified class diagram of MIGSA.
Following we present a detailed diagram of each class, including the functions that interact in each case. It should be noted that these diagrams represent a general overview of MIGSA, for a detailed explanation of each class and function please refer to the user manual.

3. Gene sets

MIGSA allows to perform the functional analysis of any type of gene sets provided by the user. Such gene sets should be present as GeneSetCollection objects from the GSEABase R library, in this section we will give a brief introduction on how to construct such an object from our own gene sets. In addition, the tools provided by MIGSA to automatically load various collections of known gene sets will be presented.

3.1. Sample GeneSetCollection creation

Here we present a simple way to create a GeneSetCollection object from own gene sets, for more detailed information please refer to the GSEABase documentation.

For this example we are going to manually create the GeneSetCollection object for the gene sets hsa00232, hsa00130 and hsa00785 from KEGG.

First, we will have to create each gene set separately, and then the GeneSetCollection object.

```r
> library(GSEABase);
```
> gs1 <- GeneSet(c("10", "1544", "1548", "1549", "1553", "7498", "9"),
+   setName="hsa00232",
+   setIdentifier="Caffeine metabolism");
> gs1;

setName: hsa00232
geneIds: 10, 1544, ..., 9 (total: 7)
geneIdType: Null
collectionType: Null
details: use 'details(object)'

> gs2 <- GeneSet(c("10229", "27235", "3242", "51004", "51805", "6898", "84274"),
+   setName="hsa00130",
+   setIdentifier="Ubiquinone and other terpenoid-quinone biosynthesis");
> gs3 <- GeneSet(c("11019", "387787", "51601"),
+   setName="hsa00785",
+   setIdentifier="Lipoic acid metabolism");
> ## And now construct the GeneSetCollection object.
> gsetsColl <- GeneSetCollection(list(gs1, gs2, gs3));
> gsetsColl;

GeneSetCollection
   names: hsa00232, hsa00130, hsa00785 (3 total)
   unique identifiers: 10, 1544, ..., 51601 (17 total)
   types in collection:
     geneIdType: NullIdentifier (1 total)
     collectionType: NullCollection (1 total)

3.2. MIGSA gene sets loading

As mentioned above, MIGSA provides functions for automatically loading known collections of gene sets. These functions are loadGo and downloadEnrichrGeneSets, the first constructs the GeneSetCollection object using the org.Hs.eg.db R package. Meanwhile, downloadEnrichrGeneSets constructs the object by downloading the gene sets from the Enrichr database (http://amp.pharm.mssm.edu/Enrichr/#stats). Enrichr gene set names can be listed with the enrichrGeneSets function.

> ## Not run:
> ## Load cellular component gene sets (another possibility would be "MF" or "BP")
> ccGsets <- loadGo("CC"); # It is a GeneSetCollection object
> ## Load KEGG and Reactome gene sets
> keggReact <- downloadEnrichrGeneSets(c("KEGG_2015", "Reactome_2015"));
> ## It is a list object containing two GeneSetCollection objects
> 
> ## End(Not run)
4. MIGSAmGSZ

4.1. mGSZ speedup

As stated below, MIGSA provides the MIGSAmGSZ function, which implements mGSZ but running much faster. In order to test MIGSAmGSZ’s correctness and speed up over mGSZ, it was evaluated using the TCGA’s microarray breast cancer dataset. Basal vs. Luminal A contrast was tested (16,207 genes x 237 subjects) over the Gene Ontology and KEGG gene sets (20,425 gene sets).

This analysis was carried out using an Intel(R) Xeon(R) E5-2620 v3 @ 2.40GHz (24 cores), 128 GB RAM. Different number of cores were used to analyze the speed up.

Let’s test it!

Note that we are using MulticoreParam as I am testing under Linux.

```r
> library(BiocParallel);
> library(mGSZ);
> library(MIGSA);
> library(MIGSAdata);
> data(tcgaMAdata);
> subtypes <- tcgaMAdata$subtypes;
> geneExpr <- tcgaMAdata$geneExpr;
> ## MA data: filter genes with less than 30% of genes read per condition
> dim(geneExpr);

[1] 16207 237

> geneExpr <- geneExpr[
+   rowSums(is.na(geneExpr[, subtypes == "Basal" ])) <
+   .3*sum(subtypes == "Basal") &
+   rowSums(is.na(geneExpr[, subtypes == "LumA" ])) <
+   .3*sum(subtypes == "LumA")
+   , ];
> dim(geneExpr);

[1] 16207 237

> ## Not run:
> ## Download GO and KEGG gene sets using MIGSA
> gSets <- list(
+   KEGG=downloadEnrichrGeneSets("KEGG_2015")[[1]],
+   BP=loadGo("BP"),
+   CC=loadGo("CC"),
+   MF=loadGo("MF"));
> gSetsList <- do.call(c, lapply(gSets, MIGSA:::asList));
> rm(gSets);
```
> nCores <- c(1,2,4,8,10,12,14);
> allRes <- lapply(nCores, function(actCores) {
+   # setting in how many cores to run
+   bp_param <- MulticoreParam(workers=actCores, threshold="DEBUG",
+                             progressbar=TRUE);
+   
+   set.seed(8818);
+   newtimeSpent <- Sys.time();
+   MIGSAmGSZres <- MIGSAmGSZ(geneExpr, gSetsList, subtypes,
+                            bp.param=bp_param);
+   newtimeSpent <- Sys.time()-newtimeSpent;
+   
+   res <- list(timeSpent=newtimeSpent, res=MIGSAmGSZres);
+   
+   return(res);
+ })
> set.seed(8818);
> timeSpent <- Sys.time();
> mGSZres <- mGSZ(geneExpr, gSetsList, subtypes);
> timeSpent <- Sys.time()-timeSpent;
> mGSZres <- mGSZres$mGSZ;
> ## this tests that the returned values are equal, must give all TRUE
> lapply(allRes, function(actRes) {
+   actRes <- actRes$res;
+   actRes <- actRes[,1:4];
+   mergedRes <- merge(mGSZres, actRes, by="gene.sets",
+                      suffixes=c("mGSZ", "MIGSAmGSZ"));
+   all(unlist(lapply(2:4, function(x) {
+     all.equal(mergedRes[,x], mergedRes[,x+3])
+   }))));
+ })
> ## End(Not run)

> ## As last chunk of code was not executed, we load that data:
> library(MIGSAdata);
> data(mGSZspeedup);
> nCores <- mGSZspeedup$nCores;
> allRes <- mGSZspeedup$allRes;
> timeSpent <- mGSZspeedup$timeSpent;
> ## End(Loading data)
>
> newtimeSpent <- lapply(allRes, function(actRes) {
+   actRes$timeSpent;
+ })
> names(newtimeSpent) <- nCores;
> speeduptable <- c(timeSpent, unlist(newtimeSpent));
names(speeduptable) <- c(1, nCores);

## Let's put all times in the same unit in order to measure speedup
newtimeSpent <- lapply(newtimeSpent, function(acttime) {
  units(acttime) <- "secs";
  return(acttime);
});

units(timeSpent) <- "secs";
speedup <- do.call(c, lapply(newtimeSpent, function(acttime) {
  as.numeric(timeSpent)/as.numeric(acttime)));
speeduptable <- rbind(speeduptable, c(1, speedup));

## calculate efficiency
speeduptable <- rbind(speeduptable,
  speeduptable[2,] / as.numeric(colnames(speeduptable)));
rownames(speeduptable) <- c("Runtime", "Speedup", "Efficiency");
round(speeduptable, 2);

<table>
<thead>
<tr>
<th>#cores</th>
<th>1</th>
<th>1.55</th>
<th>46.50</th>
<th>24.98</th>
<th>15.63</th>
<th>13.67</th>
<th>14.79</th>
<th>28.43</th>
</tr>
</thead>
<tbody>
<tr>
<td>Runtime</td>
<td>2.46h</td>
<td>1.55h</td>
<td>46.5m</td>
<td>24.98m</td>
<td>15.63m</td>
<td>13.67m</td>

<td>1.59</td>
<td>1.48</td>
<td>1.18</td>
<td>1.08</td>
<td>0.83</td>
<td>0.37</td>
</tr>
</tbody>
</table>

As it can be seen in Table 1, no matter the number of cores in which MIGSAmGSZ was tested, it outperformed mGSZ. Running in one core, it has shown a speedup of 1.6X, reaching for a top of 10.8X speedup with ten cores, giving the same results in 14 minutes in contrast to mGSZ’s 2.46 hours execution.

### 4.2. MIGSAmGSZ simple example

Following, we show how to simply execute one MIGSAmGSZ analysis.

In this example we will generate an expression matrix with 200 genes (ten differentially expressed) and eight subjects (four of condition “C1” and four of “C2”), and 50 gene sets of ten genes each one.

library(MIGSA);

## Let's create our gene expression matrix with 200 genes and 8 subjects
nSamples <- 8; # 8 subjects
nGenes <- 200; # 200 genes
geneNames <- paste("g", 1:nGenes, sep = ""); # with names g1 ... g200
## Create random gene expression data matrix.
> set.seed(8818);
> exprMatrix <- matrix(rnorm(nGenes*nSamples), ncol=nSamples);
> ## It must have rownames, as they will be treated as the gene names!
> rownames(exprMatrix) <- geneNames;
> ## There will be 10 differentially expressed genes.
> nDeGenes <- 10;
> ## Let's generate the offsets to sum to the differentially expressed genes.
> deOffsets <- matrix(2*abs(rnorm(nDeGenes*nSamples/2)), ncol=nSamples/2);
> ## Randomly select which are the DE genes.
> deIndexes <- sample(1:nGenes, nDeGenes, replace=FALSE);
> exprMatrix[deIndexes, 1:(nSamples/2)] <-
>   exprMatrix[deIndexes, 1:(nSamples/2)] + deOffsets;
> ## 4 subjects with condition C1 and 4 with C2.
> conditions <- rep(c("C1", "C2"), c(nSamples/2, nSamples/2));
> nGSets <- 50; # 50 gene sets
> ## Let's create randomly 50 gene sets, of 10 genes each
> gSets <- lapply(1:nGSets, function(i) sample(geneNames, size=10));
> names(gSets) <- paste("set", as.character(1:nGSets), sep=" ");
> ## And simply execute MIGSAmGSZ
> MIGSAmGSZres <- MIGSAmGSZ(exprMatrix, gSets, conditions);
> INFO [2018-10-30 21:47:58] Number of unique permutations: 63

> ## It is just a simple data.frame
> head(MIGSAmGSZres);

5. MIGSA simple example

Following, we show how to simply execute one MIGSA analysis.
In this example we will generate two expression matrices with 300 genes (30 differentially expressed) and 16 subjects (8 of condition “C1” and 8 of “C2”), and two sets of 30 gene sets of ten genes each one.

```r
> library(MIGSA);
> ## Let's simulate two expression matrices of 300 genes and 16 subjects.
> nGenes <- 300; # 300 genes
> nSamples <- 16; # 16 subjects
> geneNames <- paste("g", 1:nGenes, sep = ""); # with names g1 ... g300
> ## Create the random gene expression data matrices.
> set.seed(8818);
> exprData1 <- matrix(rnorm(nGenes*nSamples),ncol=nSamples);
> rownames(exprData1) <- geneNames;
> exprData2 <- matrix(rnorm(nGenes*nSamples),ncol=nSamples);
> rownames(exprData2) <- geneNames;
> ## There will be 30 differentially expressed genes.
> nDeGenes <- nGenes/10;
> ## Let's generate the offsets to sum to the differentially expressed genes.
> deOffsets <- matrix(2*abs(rnorm(nDeGenes*nSamples/2)), ncol=nSamples/2);
> ## Randomly select which are the DE genes.
> deIndexes1 <- sample(1:nGenes, nDeGenes, replace=FALSE);
> exprData1[deIndexes1, 1:(nSamples/2)] <-
+   exprData1[deIndexes1, 1:(nSamples/2)] + deOffsets;
> deIndexes2 <- sample(1:nGenes, nDeGenes, replace=FALSE);
> exprData2[deIndexes2, 1:(nSamples/2)] <-
+   exprData2[deIndexes2, 1:(nSamples/2)] + deOffsets;
> exprData1 <- new("MAList",list(M=exprData1));
> exprData2 <- new("MAList",list(M=exprData2));
> ## 8 subjects with condition C1 and 8 with C2.
> conditions <- rep(c("C1", "C2"),c(nSamples/2,nSamples/2));
> fitOpts <- FitOptions(conditions);
> nGSets <- 30; # 30 gene sets
> ## Let's create randomly 30 gene sets, of 10 genes each.
> gSets1 <- lapply(1:nGSets, function(i) sample(geneNames, size=10));
> names(gSets1) <- paste("set", as.character(1:nGSets), sep="");
> myGS1 <- as.Genesets(gSets1);
> gSets2 <- lapply(1:nGSets, function(i) sample(geneNames, size=10));
> names(gSets2) <- paste("set", as.character((nGSets+1):(2*nGSets)), sep="");
> myGS2 <- as.Genesets(gSets2);
> igsainput1 <- IGSAinput(name="igsainput1", expr_data=exprData1,
+    fit_options=fitOpts);
> igsainput2 <- IGSAinput(name="igsainput2", expr_data=exprData2,
+    fit_options=fitOpts);
> experiments <- list(igsainput1, igsainput2);
> ## As we did not set gene sets for each IGSAinput, then we will have to
> ## provide them in MIGSA function
```
## another way of generating the same MIGSA input would be setting the
gene sets individually to each IGSAinput:

```r
igsaInput1 <- IGSAinput(name="igsaInput1", expr_data=exprData1,
  + fit_options=fitOpts,
  + gene_sets_list=list(myGeneSets1=myGSs1, myGeneSets2=myGSs2));
igsaInput2 <- IGSAinput(name="igsaInput2", expr_data=exprData2,
  + fit_options=fitOpts,
  + gene_sets_list=list(myGeneSets1=myGSs1, myGeneSets2=myGSs2));
experiments <- list(igsaInput1, igsaInput2);
```

## And then simply run MIGSA

```r
migsaRes <- MIGSA(experiments);
```

> ## migsaRes contains the p-values obtained in each experiment for each gene set
> head(migsaRes);

```
   id        GS_Name igsaInput1 igsaInput2
1   set1              myGeneSets1 0.6976099 0.6706713
```
6. MIGSA’s utility

In this section we are going to demonstrate MIGSA’s utility by analyzing several well known breast cancer datasets. For each dataset, subjects were classified into breast cancer intrinsic subtypes (Basal-Like, Her2-Enriched, Luminal B, Luminal A and Normal-Like) using the PAM50 algorithm (Parker et al. 2009) by means of the pbmc R library (Fresno et al. 2016) and processed as suggested by Sorlie et al. (Sorlie et al. 2010). Only those subjects classified as Basal-Like or Luminal A were included.

Enrichment was tested over 20,245 Gene Ontology gene sets (14,291 biological processes, 1,692 cellular components and 4,263 molecular functions), and 179 from KEGG.

6.1. Used datasets

A total of eight datasets were tested, six of them were loaded by means of the pbmc R library, i.e., Mainz, Nki, Transbig, Unt, Upp and Vdx); and two were downloaded from the TCGA repository, i.e., microarray and RNAseq data matrices. For each dataset, genes reliably detected in less than 30% of the samples per condition were removed from the analysis. In addition, in RNAseq data, genes with a mean less than 15 counts per condition were also removed. Detailed datasets information can be seen in Table 2.
Table 2: Datasets details

6.2. MIGSA on TCGA data

Let's run MIGSA over the TCGA RNAseq and microarray datasets. We are going to load both datasets using the MIGSAdata package, please refer to the gettingTcgaData vignette for details about these matrices.

NOTE: This chunk of code took 29.83m to execute on 10 cores.

```r
> library(edgeR);
> library(limma);
> library(MIGSA);
> library(MIGSAdata);
> data(tcgaMAdata);
> data(tcgaRNAseqData);
> geneExpr <- tcgaMAdata$geneExpr;
> rnaSeq <- tcgaRNAseqData$rnaSeq;
> subtypes <- tcgaMAdata$subtypes; # or tcgaRNAseqData$subtypes; are the same
> fitOpts <- FitOptions(subtypes);
> ## MA data: filter genes with less than 30% of genes read per condition
> dim(geneExpr);
[1] 16207 237

> geneExpr <- geneExpr[
+   rowSums(is.na(geneExpr[, subtypes == "Basal" ])) < 
+   .3*sum(subtypes == "Basal") & 
+   rowSums(is.na(geneExpr[, subtypes == "LumA" ])) < 
+   .3*sum(subtypes == "LumA")
+   , ];
> dim(geneExpr);
[1] 16207 237

> ## create our IGSAInput object
> geneExpr <- new("MAList", list(M=geneExpr));
```
> geneExprIgsaInput <- IGSAinput(
+   name="tcgaMA",
+   expr_data=geneExpr,
+   fit_options=fitOpts,
+   # with this treat we will get around 5% differentially expressed genes
+   sea_params=SEAParams(treat_lfc=1.05));
> summary(geneExprIgsaInput);

### 6.3. MIGSA on pbcmc datasets

Let's run MIGSA over the pbcmc microarray datasets. We are going to load six datasets using the MIGSAdata package, please refer to the gettingPbcmcData vignette for details on how we got this matrices.

**NOTE:** This chunk of code took 1.27 hours to execute on 10 cores.

```>
> library(limma);
> library(MIGSA);
> library(MIGSAdata);
> data(pbcmcData);
> ## with these treat log fold change values we will get around 5% of
> ## differentially expressed genes for each experiment
> treatLfcs <- c(0.7, 0.2, 0.6, 0.25, 0.4, 0.75);
> names(treatLfcs) <- c("mainz", "nki", "transbig", "unt", "upp", "vdx");
> experiments <- lapply(names(treatLfcs), function(actName) {
+   actData <- pbcmcData[[actName]];
+   actExprs <- actData$geneExpr;
+   ```
MIGSA: Massive and Integrative Gene Set Analysis

+ actSubtypes <- actData$subtypes;
+ # filtrate genes with less than 30% per condition
+ actExprs <- actExprs[
+ rowSums(is.na(actExprs[, actSubtypes == "Basal" ])) <
+ .3*sum(actSubtypes == "Basal") &
+ rowSums(is.na(actExprs[, actSubtypes == "LumA" ])) <
+ .3*sum(actSubtypes == "LumA")
+ ],
+ ]
+ # create our IGSAinput object
+ actExprData <- new("MAList", list(M=actExprs));
+ actFitOpt <- FitOptions(actSubtypes);
+ actIgsaInput <- IGSAinput(
+ name=actName,
+ expr_data=actExprData,
+ fit_options=actFitOpt,
+ sea_params=SEAparams(treat_lfc=treatLfc[[actName]]));
+ return(actIgsaInput);
+ })

> ## Not run:
> gSets <- list(

+ BP=loadGo("BP"),
+ CC=loadGo("CC"),
+ MF=loadGo("MF"));
> set.seed(8818);
> pbcmcMigsaRes <- MIGSA(experiments, geneSets=gSets);
>
> ## Time difference of 1.26684 hours in 10 cores
> ## End(Not run)

### 6.4. MIGSA exploring breast cancer enrichment results

Let’s start with the exploratory task. First, merge both MIGSAres objects into one with all
the datasets results.

**NOTE:** In order to follow this code, sections 6.2 and 6.3 must have been executed. If not,
jump to the next “End(Not run)” tag.

> ## Not run:
> dim(pbcMcMigsaRes);
> # [1] 20425 9
## Let's merge both results in one big MIGSAres object
> bcMigsaRes <- merge(pbcmcMigsaRes, tcgaMigsaRes);
> dim(bcMigsaRes);
> # [1] 20425 11
>## End(Not run)

## As last chunk of code was not executed, we load that data:
> library(MIGSA);
> library(MIGSAdata);
> data(bcMigsaResAsList);
> bcMigsaRes <- MIGSA:::MIGSAres.data.table(bcMigsaResAsList$dframe,
+ bcMigsaResAsList$genesRank);
> rm(bcMigsaResAsList);
>## End(Loading data)
>
## Let's see a summary of enriched gene sets at different cutoff values
> summary(bcMigsaRes);

Another way of exploring the data is for example, suppose we have a list of genes of interest, we can filter our results having the gene sets that were enriched by our interest genes as follows:

```r
> consImportantGenes <- as.character(consMostEnrichedGenes$data$id);  
> intersect(tcgaImportantGenes, consImportantGenes);  

[1] "652"

> tcgaExclGenes <- setdiff(tcgaImportantGenes, consImportantGenes);
```

Another way of exploring the data is for example, suppose we have a list of genes of interest, we can filter our results having the gene sets that were enriched by our interest genes as follows:

```r
> set.seed(8818);  
> myInterestGenes <- sample(consImportantGenes, 4);  
> intGenesMigsa <- filterByGenes(bcMigsaRes, myInterestGenes);  
> dim(intGenesMigsa);
```
> head(intGenesMigsa);

<table>
<thead>
<tr>
