### 7 Session Info

### Abstract

The coupling of chromosome conformation capture (3C)-based and next-generation sequencing (NGS) enable high-throughput detection of long-range genomic interactions via the generation of novel ligation products between DNA sequences that are closely juxtaposed in vivo. These interactions may involve promoter regions, enhacers and other regulatory and structural elements of chromosomes, and can reveal key details in the regulation of gene expression. 3C-seq is a variant of the method for the detection of interactions between one chosen genomic element (viewpoint) and the rest of the genome. We present an R/Bioconductor package called  $r_3C_{seq}$ , designed to perform 3C-seq data analysis in a number of different experimental designs, with or without a control experiment. The package can also be used to perform data analysis for the experiment with replicates. The package provides functions to perform 3C-seq data normalization, statistical analysis for cis/trans interactions and visualization to facilitate the identification of genomic regions that physically interact with the given viewpoints of interest. The r3Cseq package greatly facilitates hypothesis generation and the interpretation of experimental results.

# 1 Introduction

This vignette describes how to use the r3Cseq package. r3Cseq is a Bioconductorcompliant R package designed to facilitate the identification of interaction regions generated by chromosome conformation capture and next-generation sequencing (3C-seq). The fundamental principles of 3C-seq briefly described in the following Soler et al. (2010) (Figure 1), isolated cells are treated with a cross-linking agent to preserve in vivo nuclear proximity between DNA sequences. The DNA isolated from these cells is then digested using a primary restriction enzyme, typically a 6-base pairs cutting enzyme such as HindIII, EcoRI or BamHI. The digested product is then ligated under dilute conditions to favor intra-molecular over inter-molecular ligation events. This digested and ligated chromatin yields composite sequences representing (distal) genomic regions that are in close physical proximity in the cell nucleus. The digested and ligated chromatin is then de-crosslinked and subjected to a second restriction digest using either Nla III or Dpn II (a 4-cutter) as a secondary restriction enzyme to decrease the fragment sizes. The resulting digested DNA is then ligated again under diluted conditions, creating small circular fragments. These fragments are inverse PCR-amplified using primers specific for a genomic region of interest (eg. promoter, enhancer, or any other element potentially involved in long-range interactions), termed the "viewpoint". The amplified fragments are then sequenced using massively parallel high-throughput sequencing. Because the 3Cseq procedure hybrid DNA molecules being a combination of viewpoint-specific primers followed by sequences dervied from the ligated interaction fragments. As such, these composite sequences are unmappable and need to be trimmed to removed the viewpoint

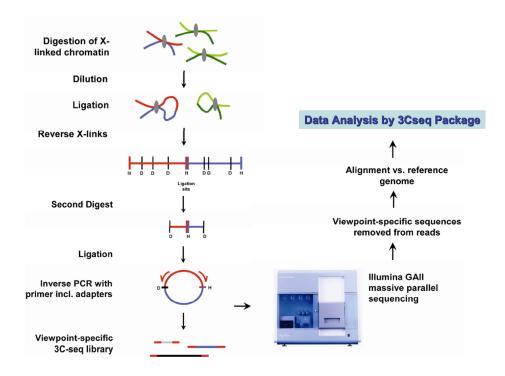

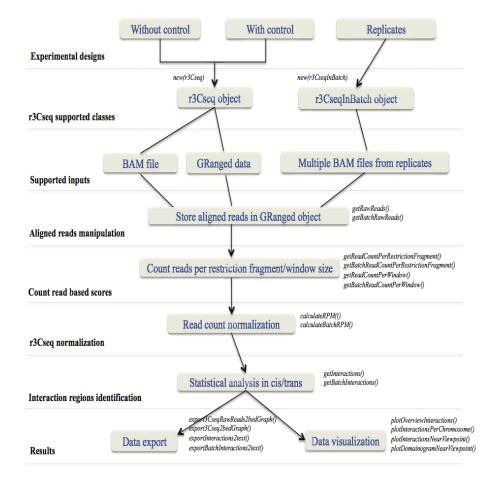

Figure 1: 3C-seq procedures

sequences, thus leaving only the capture sequence fragments for mapping. After trimming, reads are mapped against a reference genome using alignment software such as Bowtie. A mapped read file generated by the mapping software is then transformed to the BAM file and analyzed by using r3Cseq package.

r3Cseq package is built on, and extends the functionality of Bioconductor package such as *GenomicRanges*, *BSgenome*, *Rsamtools*, and *rtracklayer*. The package provides classes and methods to facilitate single-end reads, which are generated by the nextgeneration sequencing. The package can perform data analysis on both single input file (single lane from one experiment) and two input files from an experiment and a control. The package also provides a class and functions to perform 3C-seq data analysis from replicates (see working with replicates section). The key features workflow of r3Cseqdepicts in the following figure. (Figure 2)

r3Cseq analysis workflow starts from the class initialization. There are two classes found in this package. One is r3Cseq class that is designed to support a single experiment in both with and without a control experiment. Another is r3CseqInBatch class that is designed to support analysis with replicates. To initialize the class both r3Cseq and r3CseqInBatch, a user gives the input parameters for example the input file name, genome assembly version, primary restriction fragment name and so on (see more details in the manual page of r3Cseq and r3CseqInBatch). The class is then will be created and it is ready to perform 3C-seq analysis. The getRawReads and getRawReadsInBatch functions can be next used to read in the BAM files. It may take

### r3C-Seq key features workflow

Figure 2: r3Cseq key features workflow

a few minutes for data processing depending on the size of the input BAM files and the speed of CPU and the size of the RAM of a computer that performs analysis. To run the getRawReadsInBatch function for replicates, a user might have a powerful computer server. getRawReads function reads in aligned reads from input BAM files and transforms aligned reads to the **GRanged** objects that can be stored in the r3Cseq object, whereas getRawReadsInBatch processes the data in batch and stores the aligned reads **GRanges** in the R files (.rdata). To count number of reads preparing for downstream analysis, r3Cseq provides two ways to count number of reads per region; 1) count number of reads per resitrction fragments, using the function getReadCount-**PerRestrictionFragment** and 2) count the number of reads per non-overlapping window size, using function getReadCountPerWindow, whereas getBatchReadCountPer-RestrictionFragment and getBatchReadCountPerWindow can do the same for replicates. r3Cseq provides calculateRPM and calculateBatchRPM functions to calculate reads per million per restriction fragment size (RPM) as normalized interaction frequency values. There are two methods to calculate RPM, which are described in the r3Cseq paper ?. After data normalization, getInteractions and getBatchInteractions will be performed to identify candidate interactions. Statistical analysis for both cis and trans interactions is described in the r3Cseq paper ?. r3Cseq provides functions export3CseqRawReads2BedGraph, export3Cseq2bedGraph, exportInteractions2text, and exportBatchInteractions2text to export raw reads and all identified interactions to the bedGraph file format, which is simply uploaded to the UCSC genome browser. The package also provides functionalities for plotting to show data analysis result of interaction regions. Plotting functions consist of plotOverviewInteractions, plotInteractionPerChromosome, plotInteractionNearViewpoint, and plotDomainogram-NearViewpoint. These functions will be demonstrated in the visualization of 3C-seq data section.

Here is a list of some of its most important functions.

- 1. getRawReads: a function to read in BAM files.
- 2. getBatchRawReads: a function to read in multiple BAM files for replicates.
- 3. getReadCountPerRestrictionFragment : a function to count the number of reads per restriction fragment. A user has to specify the name of restriction enzyme. The package will then automatically generate the genome-wide restriction fragments and counts how many 3C-seq reads are mapped into that particular restriction fragments.
- 4. getBatchReadCountPerRestrictionFragment : Similar to getReadCountPerRestrictionFragment using it for replicates
- 5. getReadCountPerWindow : a function to count the number of reads per defined non-overalapping window size. A user has to specify the window size of interest.

The package will then automatically generate the genome-wide windows and counts how many 3C-seq reads are mapped into that particular windows.

- 6. getBatchReadCountPerWindow : similar to getReadCountPerWindow using for replicates
- 7. calculateRPM : a function to calcuate reads per million (RPM) per each restriction fragment
- 8. calculateBatchRPM : similar to calculateRPM using for replicates
- 9. getInteractions : a function to perform statistical analysis to identify candidate interactions
- 10. getBatchInteractions : similar to getInteractions using for replicates
- 11. *Visualiztion*: the package contains functions for visualizing the interaction regions with the powerful plotting facilities. These functions are plotOverviewInteractions, plotInteractionsNearViewpoint,plotInteractionsPerChromosome, and plotDomainogramNearViewpoint.
- 12. Data export : the package contains functions to export the data into tab-delimited text format, which can be easily uploaded to the UCSC genome browser for further visualization and exploration. Currently it supports the bedGraph format. These functions are export3CseqRawReads2bedGraph, export3Cseq2bedGraph, exportInteractions2text, exportBatchInteractions2text. The package can also generate a summary report in PDF format by generate3CseqReport function.

# 2 Preparation input files for r3Cseq

The required input file for r3Cseq package is the BAM file, obtained as an output from the mapping software. The represented identifier for a reference genome shown in each input BAM file is important to run r3Cseq properly. The represented identifier for each chromosome must be in "chr[1..19XYM]" format for the mouse reference genome and "chr[1..22XYM]" format for the human reference genome. Therefore, before using r3Cseq package, a user has to check the identifier for the reference genome. If the identifier for each chromosome found in the mapped file is not in a proper format for example 'mm9\_ref\_chr01.fa', the Unix command like 'sed' might be used to replace 'mm9\_ref\_chr01.fa' to 'chr1'.

# 3 Getting started

The 3C-seq data generated by ? will be used for the demonstration. The current version of r3Cseq supports mouse, human, and rat genomes. Therefore, the package requires one

of the followings BSgenome packages to be installed; BSgenome. Mmusculus. UCSC.mm9.masked, BSgenome.Mmusculus. UCSC.mm10.masked, BSgenome.Hsapiens. UCSC.hg18.masked, BSgenome.Hsapie and BSgenome.Rnorvegicus. UCSC.rn5.masked.

Loading the r3Cseq package into R.

### > library(r3Cseq)

There are 2 data sets found in the package.

```
> data(Myb_prom_FL)
```

```
> data(Myb_prom_FB)
```

- 1. Myb\_prom\_FL, the 3C-seq data contains the aligned reads of the Myb promoter interactions signal in fetal liver. It was stored in the GRanges object processed by the *Rsamtools* package.
- 2. Myb\_prom\_FB, the 3C-seq data contains the aligned reads of Myb promoter interactions signal in fetal brain.

We will perform r3Cseq to discover interaction regions, which possibly interact with the promoter region of Myb gene in both fetal liver and brain ?.

# 3.1 r3Cseq object initialization

In this section, we will analyze 3C-seq data, which were derived from fetal liver (expressing high levels of Myb) and fetal brain (expression low level of Myb). The latter will be used as a negative control. More examples of r3Cseq data analysis can be found at the official r3Cseq website http://r3cseq.genereg.net. We firstly initialized the r3Cseq object.

```
> my3Cseq.obj<-new("r3Cseq",organismName='mm9',isControlInvolved=TRUE,
```

```
+ viewpoint_chromosome='chr10',viewpoint_primer_forward='TCTTTGTTTGATGGCATCTGTT',
```

```
+ contrLabel="MYb_prom_FB",restrictionEnzyme='HindIII')
```

Definition of input parameters is described in the r3Cseq help page. We next add raw reads from Myb\_prom\_FL and Myb\_prom\_FB to the existing my3Cseq.obj.

```
> expRawData(my3Cseq.obj)<-exp.GRanges</pre>
```

```
> contrRawData(my3Cseq.obj)<-contr.GRanges</pre>
```

Type my3Cseq.obj to see the r3Cseq object:

```
> my3Cseq.obj
```

# 3.2 Getting reads per restriction fragments/user defined window size

To get number of reads per restriction fragement, function getReadCountPerRestrictionFragment will be performed. > getReadCountPerRestrictionFragment(my3Cseq.obj)

```
[1] "Fragmenting genome by....HindIII...."
```

[1] "Count processing in the experiment is done."

[1] "Count processing in the control is done."

The package provides the function getReadCountPerWindow to count number of reads per non-overlapping window size defined by a user.

### 3.3 Normalization

We next perform normalization.

```
> calculateRPM(my3Cseq.obj)
```

[1] "Normal RPM calculation is done."

# 3.4 Getting interaction regions

After normalization, the getInteractions function will be performed.

```
> getInteractions(my3Cseq.obj,fdr=0.05)
```

[1] "Calculation is done. Use function 'expInteractionRegions' or 'contrInteractionRegi

In order to see the result of interaction regions, Two functions expInteractionRegions and contrInteractionRegions need to be used to access the slot of r3Cseq object. To get the result of interaction regions for the experiment, expInteractionRegions will be performed.

```
> fetal.liver.interactions<-expInteractionRegions(my3Cseq.obj)
> fetal.liver.interactions
```

GRanges object with 19502 ranges and 5 metadata columns:

### 3.5 Getting the viewpoint information

To see the viewpoint information, getViewpoint function can be used. getViewpoint will return the RangedData object of the viewpoint information.

# > viewpoint<-getViewpoint(my3Cseq.obj) > viewpoint

# 4 Visualization of 3C-seq data

*r3Cseq* package provides visualization functions. These functions are plotOverviewIn-teractions, plotInteractionsNearViewpoint, plotInteractionsPerChromosome, and PlotDomainogramNearViewpoint.

### 4.1 The overview plot of interactions

plotOverviewInteractions function shows the overview of interaction regions distributed across genome.

> plotOverviewInteractions(my3Cseq.obj)

3C-seq distribution of interaction regions (q-value <= 0.05 )

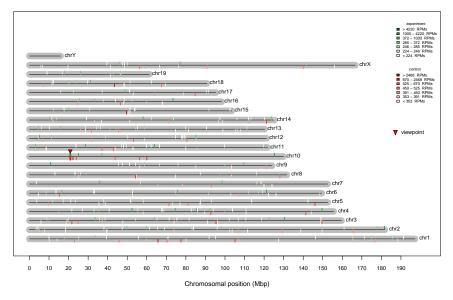

Figure 3: Distribution of interaction regions across genome

# 4.2 Plot of interactions in cis

plotInteractionsNearViewpoint function shows the zoom in of interaction regions located close to the viewpoint.

> plotInteractionsNearViewpoint(my3Cseq.obj)

# 4.3 Plot of interactions in each selected chromosome

plotInteractionsPerChromosome function shows the interaction regions found in the chromosome10.

> plotInteractionsPerChromosome(my3Cseq.obj,"chr10")

# 4.4 Domainogram of interactions

plotDomainogramNearViewpoint function shows the domainogram of interactions found in cis. This function may takes several minutes to produce domainograms. We therefore, skip this command to produce plots for the vignette. You can see the example of the plots and find more details at http://r3Cseq.genereg.net.

```
> #plotDomainogramNearViewpoint(my3Cseq.obj)
```

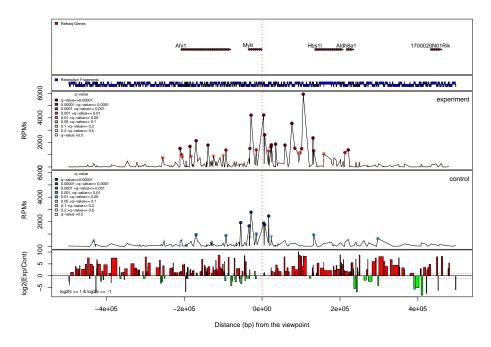

Figure 4: Zoom in interaction regions near the viewpoint

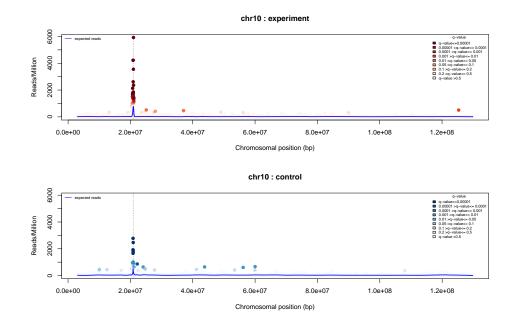

Figure 5: Distribution of interaction regions across chromosome 10

# 4.5 Associate interaction signals to the Refseq genes

getExpInteractionsInRefseq and getContrInteractionsInRefseq functions can be used to detect the list of genes that contain significant interaction signals in their proximity.

```
> detected_genes<-getExpInteractionsInRefseq(my3Cseq.obj)</pre>
```

```
> head(detected_genes)
```

	chromosome	gene_name	total_nReads	total_RPMs
173	chr10	Myb	43217	20539.955
143	chr10	Hbs11	34310	16031.869
29	chr10	Ahi1	29738	11912.850
135	chr4	Gm5506	15792	3939.331
33	chr10	Aldh8a1	9422	3633.383
137	chr4	Gm5801	13482	3350.087

# 4.6 Export interactions to the bedGraph format

export3Cseq2bedGraph function exports all interactions from the RangedData to the bedGraph format, which simply upload to the UCSC genome browser.

```
> #export3Cseq2bedGraph(my3Cseq.obj)
```

# 4.7 Summary report

generate3CseqReport function generates the summary report from r3Cseq analysis results. The report contains a pdf file for all plots and text files of interaction regions. This function may takes several minutes to produce the report. We therefore, skip this command during the vignette creation.

```
> #generate3CseqReport(my3Cseq.obj)
```

# 5 Working with replicates

The example of how to work with replicats can be found at http://r3cseq.genereg.net/.

# 6 r3Cseq website

We have developed the website http://r3cseq.genereg.net. The website provides more details of r3Cseq analysis pipeline. The example data sets and the current version of r3Cseq package can be downloaded from the website.

# 7 Session Info
