13.1 Introduction
13.2 Analyzing Longitudinal Data
13.3 Analysis Using R

We shall fit both random intercept and random intercept and slope models to the data including the baseline BDI values (pre.bdi), treatment group, drug, and length as fixed effect covariates. Linear mixed effects models are fitted in R by using the lmer function contained in the lme4 package (Bates and Sarkar, 2014; Pinheiro and Bates, 2000; Bates, 2005), but an essential first step is to rearrange the data from the ‘wide form’ in which they appear in the BtheB data frame into the ‘long form’ in which each separate repeated measurement and associated covariate values appear as a separate row in a data.frame. This rearrangement can be made using the following code:

```R
> data("BtheB", package = "HSAUR3")
> BtheB$subject <- factor(rownames(BtheB))
> nobs <- nrow(BtheB)
> BtheB_long <- reshape(BtheB, idvar = "subject", 
+ varying = c("bdi.2m", "bdi.3m", "bdi.5m", "bdi.8m"), 
+ direction = "long")
> BtheB_long$time <- rep(c(2, 3, 5, 8), rep(nobs, 4))
```

such that the data are now in the form (here shown for the first three subjects)

```R
> subset(BtheB_long, subject %in% c("1", "2", "3"))
```

<table>

</tbody>
</table>

The resulting data.frame BtheB_long contains a number of missing values
```r
R> data("BtheB", package = "HSAUR3")
R> layout(matrix(1:2, nrow = 1))
R> ylim <- range(BtheB[,grep("bdi", names(BtheB))],
+ na.rm = TRUE)
R> tau <- subset(BtheB, treatment == "TAU")[, grep("bdi", names(BtheB))]
R> boxplot(tau, main = "Treated as Usual", ylab = "BDI",
+ xlab = "Time (in months)", names = c(0, 2, 3, 5, 8),
+ ylim = ylim)
R> btheb <- subset(BtheB, treatment == "BtheB")[, grep("bdi", names(BtheB))]
R> boxplot(btheb, main = "Beat the Blues", ylab = "BDI",
+ xlab = "Time (in months)", names = c(0, 2, 3, 5, 8),
+ ylim = ylim)
```

![Boxplots for the repeated measures by treatment group for the BtheB data.](image)

Figure 13.1  Boxplots for the repeated measures by treatment group for the BtheB data.

and in applying the `lmer` function these will be dropped. But notice it is only the missing values that are removed, not participants that have at least one missing value. All the available data is used in the model fitting process. The `lmer` function is used in a similar way to the `lm` function met in Chapter 6 with the addition of a random term to identify the source of the repeated measurements, here `subject`. We can fit the two models (??) and (??) and test which is most appropriate using

```r
R> library("lme4")
```

Figure 13.2 R output of the linear mixed-effects model fit for the BtheB data.

The summary method for lmer objects doesn’t print p-values for Gaussian mixed models because the degrees of freedom of the t reference distribution are...
not obvious. However, one can rely on the asymptotic normal distribution for computing univariate \( p \)-values for the fixed effects using the `cftest` function from package `multcomp`. The asymptotic \( p \)-values are given in Figure 13.3.

```r
R> cftest(BtheB_lmer1)
Simultaneous Tests for General Linear Hypotheses
Fit: lmer(formula = bdi ~ bdi.pre + time + treatment + drug + length +
(1 | subject), data = BtheB_long, REML = FALSE, na.action = na.omit)

bdi.pre == 0 0.63968 0.07789 8.212  2.22e-16

time == 0 -0.70476 0.14639 -4.814  1.48e-06
treatmentBtheB == 0 -2.32908 1.67036 -1.394  0.1632
drugYes == 0 -2.82495 1.72684 -1.636  0.1019
length>6m == 0 0.19708 1.63832  0.120  0.9043
(Univariate p values reported)
```

**Figure 13.3** R output of the asymptotic \( p \)-values for linear mixed-effects model fit for the BtheB data.

We can check the assumptions of the final model fitted to the BtheB data, i.e., the normality of the random effect terms and the residuals, by first using the `ranef` method to predict the former and the `residuals` method to calculate the differences between the observed data values and the fitted values, and then using normal probability plots on each. How the random effects are predicted is explained briefly in Section ??, The necessary R code to obtain the effects, residuals, and plots is shown with Figure 13.4. There appear to be no large departures from linearity in either plot.
ANALYSIS USING R

R> layout(matrix(1:2, ncol = 2))
R> qint <- ranef(BtheB_lmer1)$subject[['(Intercept)']]
R> qres <- residuals(BtheB_lmer1)
R> qqnorm(qint, ylab = "Estimated random intercepts",
+     xlim = c(-3, 3), ylim = c(-20, 20),
+     main = "Random intercepts")
R> qqline(qint)
R> qqnorm(qres, xlim = c(-3, 3), ylim = c(-20, 20),
+     ylab = "Estimated residuals",
+     main = "Residuals")
R> qqline(qres)
