

Comparing the performance of a panel of candidate interim monitoring schemes over a range of hypothetical trial scenarios, using `cpd.PwrGSD` (Version 1.16)

Grant Izmirlan

April 3, 2012

1 Introduction

The selection of a test statistic and boundary construction method in the design of an interim monitoring plan is done by computing several operating characteristics, such as power, expected duration and relative risks at the stopping boundaries, for each candidate plan under a variety of hypothetical trial scenarios and under various options for boundary construction. Thus one wishes to optimize, in the sense of best overall performance over a range of trial scenarios, these operating characteristics with respect to the variables over which one has control. There is usually not a unique optimal choice, especially if the user is realistic about the range of trial scenarios. However, if one chooses a balance of behavior under favorable scenarios and under unfavorable scenarios, and the investigation has appealed to a rich enough variety of appropriate choices, an acceptable monitoring scheme will be found.

In order to understand this vignette, you should familiarize yourself with the function **PwrGSD** which computes these operating characteristics for a specification of the trial scenario (which admits non-proportional hazards alternatives through the specification of control and intervention arm specific piecewise constant hazard rates for the main event, censoring, and two modes of non-compliance), choice of test statistic and choice of boundary construction method. Refer to the help pages by typing `?PwrGSD` within R.

The `cpd.PwrGSD` function and its related class provide a infrastructure whereby the behavior of the above-mentioned operating characteristics as the choice of statistic, boundary construction method (design space) and hypothetical trial scenarios (outcome space) vary can be flexibly determined and then conveniently summarized. To summarize the idea, note that the function `cpd.PwrGSD` takes as its sole argument a `data.frame`, the descriptor, with a complete specification of a point in the design by outcome space per line and creates as output, a skeleton object of class `cpd.PwrGSD` as its output. The most important component of this output (a list of class `cpd.PwrGSD`) is the component **Elements**. This starts life as a list, with `NULL` components, of length equal to the number of rows of the descriptor `data.frame`. The functionality of this infrastructure to summarize, i.e. in the form of a trellis plot, for example, comes from the implicit cross-linking between the components of **Elements** and the rows of the descriptor `data.frame`. The flexibility of this infrastructure owes to the fact that it is completely user determined. The exact meaning of this will become apparent in the example below. The full extent of the capabilities can be well understood by absorbing the capabilities of **PwrGSD**, which computes operating characteristics for a single point in design by outcome space.

In order to set up a compound object of class `cpd.PwrGSD` we first construct a base case: a two arm trial randomized in just under eight years with a maximum of 20 years of follow-up. We compute power at a specific alternative, **rhaz**, under an interim analysis plan with roughly one analysis per year, some crossover between intervention and control arms, with Efficacy and futility boundaries constructed via the Lan-Demets procedure with O'Brien-Fleming spending on the hybrid scale. We investigate the behavior of three weighted log-rank statistics: (i) the Fleming-Harrington(0,1) statistic, (ii) a stopped version of the F-H(0,1) statistic capped off at 10 years, and (iii) the deterministic weighting function with linear increase between time 0 and time 10 with constant weight thereafter.

```

> tlook <- c(7.14, 8.14, 9.14, 10.14, 10.64, 11.15, 12.14, 13.14,
+           14.14, 15.14, 16.14, 17.14, 18.14, 19.14, 20.14)
> t0 <- 0:19
> h0 <- c(rep(3.73e-04, 2), rep(7.45e-04, 3), rep(1.49e-03, 15))
> rhaz <-c(1, 0.9125, 0.8688, 0.7814, 0.6941, 0.6943, 0.6072, 0.5202,
+          0.4332, 0.652, 0.6524, 0.6527, 0.653, 0.6534, 0.6537,
+          0.6541, 0.6544, 0.6547, 0.6551, 0.6554)
> hc <- c(rep(1.05e-02, 2), rep(2.09e-02, 3), rep(4.19e-02, 15))
> hd1B <- c(0.1109, 0.1381, 0.1485, 0.1637, 0.2446, 0.2497, 0)

> library(PwrGSD)
> test.example <-
+   PwrGSD(EfficacyBoundary=LanDemets(alpha=0.05, spending= ObrienFleming),
+         FutilityBoundary=LanDemets(alpha=0.1,spending=ObrienFleming),
+         RR.Futility = 0.82, sided="1<",method="A",accru =7.73, accrat=9818.65,
+         tlook =tlook, tcut0 =t0, h0=h0, tcut1=t0, rhaz=rhaz,
+         tcutc0=t0, hc0=hc, tcutc1=t0, hc1=hc,
+         tcutd0B =c(0, 13), hd0B =c(0.04777, 0),
+         tcutd1B =0:6, hd1B =hd1B,
+         noncompliance =crossover, gradual =TRUE,
+         WtFun =c("FH", "SFH", "Ramp"),
+         ppar =c(0, 1, 0, 1, 10, 10))

```

Now **test.example**, containing the computed operating characteristics corresponding to our “base case” single point in design by outcome space in the form of the resulting call to **PwrGSD**. Then we (the user) decide how we wish to explore the design by outcome space by determining which pieces of the picture we want to range over. In the following we vary (i) the alternative hypothesis by stipulating 9 values of the maximum effect, (ii) the censoring amount by stipulating 3 values, and (iii) the boundary construction method, as two efficacy boundary construction methods: Lan-Demets with Obrien-Fleming spending and stochastic curtailment. Each of these will be incorporated as a simple modification to the base case above.

First, the vector of possible maximum effects for varying the alternative hypothesis:

```

> max.effect <- 0.80 + 0.05*(0:8)
> n.me <- length(max.effect)

```

Next the vector of censoring amounts:

```

> cens.amt <- 0.75 + 0.25*(0:2)
> n.ca <- length(cens.amt)

```

Our candidate monitoring plans use the Lan-Demets boundary construction method. We wish to compare O’Brien-Fleming spending with linear spending:

```

> Eff.bound.choice <- 1:2
> ebc.nms <- c("LanDemets(alpha=0.05, spending=ObrienFleming)",
+            "LanDemets(alpha=0.05, spending=Pow(1))")
> n.ec <- length(Eff.bound.choice)

```

Next we create the descriptor data.frame, with one line corresponding to each of the possible $9 * 3 * 2$ possible choices. This is done in the following line.

```

> descr <- as.data.frame(
+   cbind(Eff.bound.choice=rep(Eff.bound.choice, each=n.ca*n.me),
+         cens.amt=rep(rep(cens.amt, each=n.me), n.ec),
+         max.effect=rep(max.effect, n.ec*n.ca)))
> descr$Eff.bound.choice <- ebc.nms[descr[["Eff.bound.choice"]]

```

Now the descriptor data.frame, **descr** contains one row for each combination of the levels of the user defined selection variables, **Eff.bound.choice**, **max.effect** and **cens.amt**. Keep in mind that the names and number of these variables is arbitrary. Next we create a skeleton **cpd.PwrGSD** object with a call to the function **cpd.PwrGSD** with argument **descr**

```
> test.example.set <- cpd.PwrGSD(descr)
```

Now, the newly created object, of class **cpd.PwrGSD**, contains an element **descr**, a component **date**, the date created and a component **Elements**, an empty list of length equal to the number of rows in **descr**. Next we do the computation in a loop over the rows of **descr**. Inside the loop we execute the following steps for each *k*. In the first line, we copy the original call to the current call, **Elements[[k]]\$call**. In the second line, we use the efficacy boundary choice in the *k*th row of **descr** to set the efficacy boundary choice in the current call. In the third line, we derive the **rhaz** defined by the selection variable **max.effect** in the *k*th row of **descr** and use this to set the **rhaz** component of the current call. In the fourth line, we derive the censoring components from the selection variable **cens.amt** in the *k*th row of **descr** and place that result into the current call. In this manner we have constructed a call to **PwrGSD** that corresponds exactly to the selection variable values in row *k* of **descr**. The computation is done by calling **update**:

```
> n.descr <- nrow(descr)
> for(k in 1:n.descr){
+
+   test.example.set$Elements[[k]]$call <- test.example$call
+
+   test.example.set$Elements[[k]]$call$EfficacyBoundary <-
+     parse(text=as.character(descr[k,"Eff.bound.choice"]))[[1]]
+
+   test.example.set$Elements[[k]]$call$rhaz <-
+     exp(descr[k,"max.effect"] * log(rhaz))
+
+   test.example.set$Elements[[k]]$call$hc0 <- descr[k, "cens.amt"] * hc
+   test.example.set$Elements[[k]]$call$hc1 <- descr[k, "cens.amt"] * hc
+
+   test.example.set$Elements[[k]] <- update(test.example.set$Elements[[k]])
+ }
```

The functionality of this cross-linked list **PwrGSD** elements and a descriptor data.frame is the ability to extract subsets of this list through the specification of subsets of the descriptor data.frame. For example the following creates a new **cpd.PwrGSD** object by subsetting on the selection variables in **descr** as the first line below.

```
> test.example.subset <-
+   Elements(test.example.set,
+             subset=(substring(Eff.bound.choice, 32, 34)=="Obr" &
+                             max.effect >= 1))
```

The plot method for **cpd.PwrGSD** produces trellised stacked plots of power and type II error at each analysis versus the magnitude of effect conditioned on the values of two other descriptor variables.

This is done via a formula argument of the form $\sim x \mid a$ or $\sim x \mid a*b$ which specify, a stacked plot of power and type II error as the magnitude of effect, *x* varies, that is conditioned on values of *a* alone, in the first case, and *a* by *b* in the second case, respectively. Subsetting is also allowed. In the first plot, 1, we have subsetted to the elements in which Lan-Demets/O'Brien-Fleming efficacy boundary was used, while in the second plot, 2, we have subsetted to the elements in which Lan-Demets/linear spending efficacy boundaries were used.

```
> plot(test.example.set, formula = ~ max.effect | stat * cens.amt,
+       subset=(substring(Eff.bound.choice, 32, 34)=="Obr"))
```

Figure 1: Power (cyan) and type II error (magenta) at each analysis versus the maximum benefit. Lan-Demets efficacy and futility boundary using Obrien-Fleming spending.

```
> plot(test.example.set, formula = ~ max.effect | stat * cens.amt,
+       subset=(substring(Eff.bound.choice, 32, 34)=="Pow"))
```

Notice the appearance of the selection variable **stat** which was not defined in the dataset **descr**. Recall that each single **PwrGSD** object can contain results for a list of test statistics, as in the example shown here where we have results on three statistics per component of **Elements**. For this reason the variable **stat** can be also be referenced in the **subset** or **formula** arguments of calls to this **plot** method.

Figure 2: Power (cyan) and type II error (magenta) at each analysis versus the maximum benefit. Lan-Demets efficacy and futility boundary, using linear spending and O'Brien-Fleming spending respectively.
